Embedded System Workshops

02. Digital Inputs: Buttons *CCA Girls Who Code*

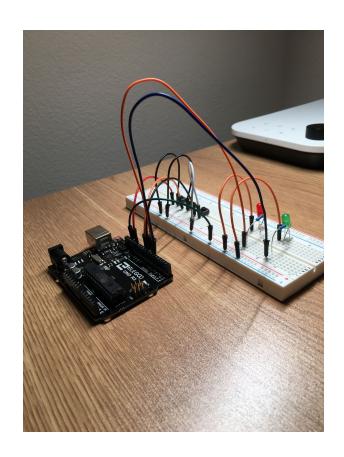

Project Overview

- Purpose
 - Introduce digital inputs such as buttons
 - Use such inputs in a circuit
- → Projects
 - Simple circuit with button
 - Button passcode project
- Grab your kit, and let's get started!

What are we making?

- → Button passcode project
 - Use a series of buttons to input a "password"
 - If the right password is input, a green LED turns on for a few seconds
 - If the wrong password is input, a red LED turns on for a few seconds
 - Can try again if needed

Parts List

Below is the list of parts we'll be using during this lesson

- → Arduino UNO R3 Controller Board
- → USB Cable
- → Breadboard
- → 2 LEDs
- \rightarrow 2 220 Ω Resistors
- → Male-male jumper wires
- → 3 Buttons

What are Switches?

A switch is a device that you can use to open or close a circuit at will. A closed circuit allows current to flow through it. An open circuit has a gap in the circuit, preventing current from flowing through it.

Why is this relevant?

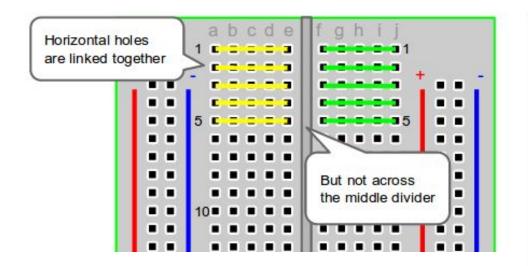

A button is a type of switch that closes the circuit when pressed down and opens it when released.

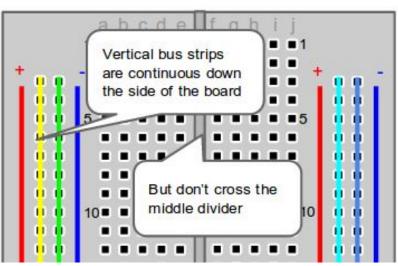

A button

Review

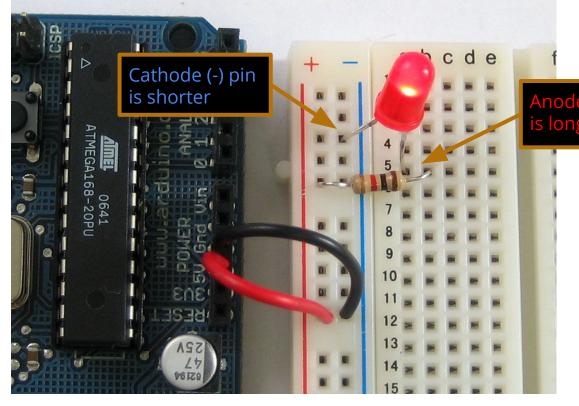

Breadboards Explained

Tip: It is good practice to have your power input connected to the red/positive rail and your ground pin connected to the blue/negative rail.

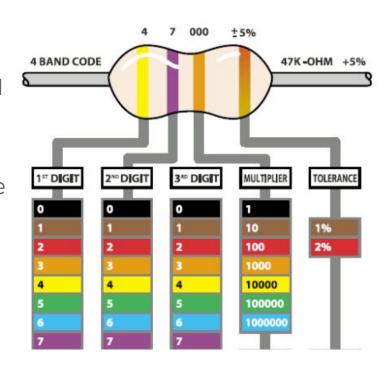

LEDs

NOTE: Make sure the power input is connected to the Anode, and the ground pin is connected to the Cathode. Make sure you also have a resistor between either the power input and Anode, or the Cathode and ground pin. Failing to do either of these things can damage the LED or the Arduino.

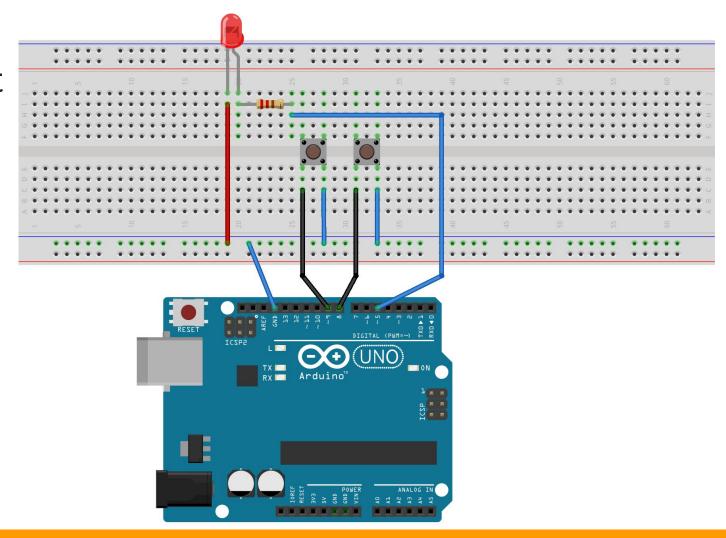

Resistors

- Resistors slow the electric current, and control where and how fast the current flows
- Resistance value is measured in ohms Ω , which is represented by colored stripes on the body of the resistor
- Each stripe has a different value depending on the color and location as shown in the reference chart
- A potentiometer is a variable resistor

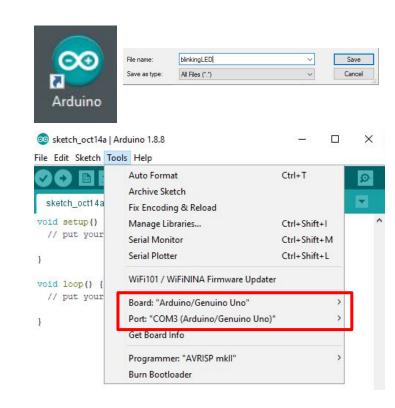

Project

Digital Input Schematic

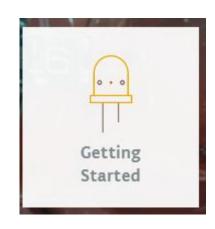

Setting up Arduino

- Find and open Arduino on your desktop
- Click "File" in the top left corner and click save
- Save this tab as "digitalInputs"
- Connect the USB cord in your kit to the Arduino and the computer (USB port is on the left side of the monitor)
- → Open the "Tools" Window and make sure the board has been recognized and the port is "COM#" with the name of the board after it

Setting up Arduino (Online Web Editor)

- → Search up create.arduino.cc
- Click Getting Started
- Scroll all the way down and click "Set up the Arduino Plugin"
- Click Next and follow the steps to download the plugin

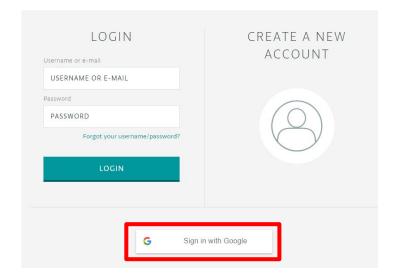

- ***
- → If it doesn't automatically bring you to the login screen, click the 9 dots in the upper left hand corner and click Arduino Web Editor.

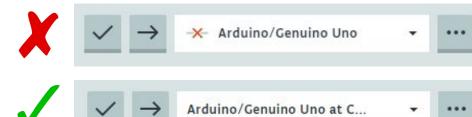

- → Click the Sign in with Google button
- Sign in with your Google account
 - You must use a personal email!

Getting Started

- → Click "NEW SKETCH" in the top left corner
- → Click on the sketch name and rename it "digitalInput"
- Connect the USB cord in your kit to the Arduino and the computer
- → The type of Arduino should have been recognized. If not, please type in chat.

Digital Inputs

ledPin, buttonAPin, and buttonBPin are variables of the data type int, meaning they hold integer values.

Each corresponds to a **pin number** on the Arduino.

To test your code, click the checkmark then the arrow!

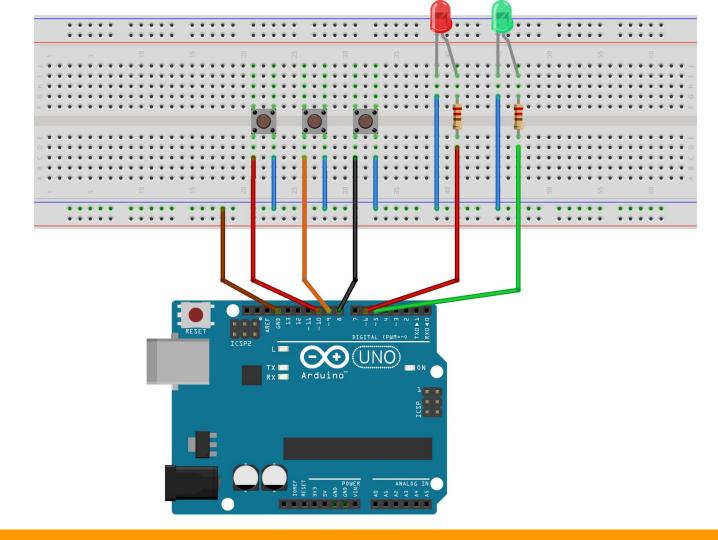

digital_inputs

```
int ledPin = 5; // single LED pin
int buttonAPin = 9; // the left button
int buttonBPin = 8; // the right button
void setup() {
 // set buttons to be used as an input
 pinMode (ledPin, OUTPUT);
 pinMode (buttonAPin, INPUT PULLUP);
 pinMode (buttonBPin, INPUT PULLUP);
void loop() {
 if (digitalRead(buttonAPin) == LOW) {
    digitalWrite (ledPin, HIGH);
  if (digitalRead(buttonBPin) == LOW) {
    digitalWrite (ledPin, LOW);
```

The setup() function sets the led as an **output** device and the buttons as **input** devices.

The loop() function states that if **buttonA** is pushed, turn the LED **ON**. If **buttonB** is pushed, turn the LED **OFF**.

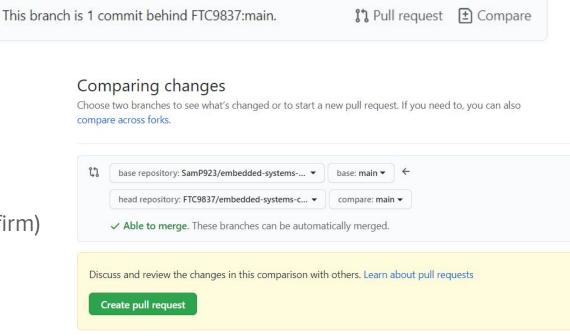

Passcode Schematic

Grab the Starter Code from GitHub

If you haven't made the repository yet, check these slides

- → Go to your repository (username/embedded-systems-course)
- Click "Compare"
- Switch the repos so yours
 is the base repository and
 FTC9837 is the head
- → Create pull request (x2)
- Merge pull request (and confirm)
- You should have the lesson2 folder in your repository

Passcode Code - setup()

Open the button_passcode.ino file that you pulled from GitHub on your local system.

The variable declarations and setup() function similarly to the digital_inputs file

button_passcode

```
// set pins for LEDs and buttons
int green led pin = 5;
int red led pin = 6;
int buttons[3] = {8,9,10};
// set hardcoded password
int passcode arr[]= {0,1,2,0,0,0};
// store size of password array
const int SIZE = sizeof(passcode arr) / sizeof(int);
// store user inputs
int states[SIZE];
int index state = 0;
void setup() {
  // set leds as output and buttons as input
 pinMode (green led pin, OUTPUT);
  pinMode (red led pin, OUTPUT);
  for (int i = 0; i<3; i++) {
    pinMode (buttons[i], INPUT PULLUP);
  Serial.begin (9600);
  Serial.println("Good to go!");
```

The array
passcode_arr[]
sets the values of
the correct
passcode and
size stores the
length of it.

Passcode Code - loop() Part 1

Each of the if-statements checks if a **specific** button was pressed.

If so, add that to the array **states** that holds the user input, and print the number to the **Serial** Monitor so we can verify the input.

```
void loop() {
  // check if inputs are pushed -- if so, add to the states array
  if (digitalRead(buttons[0]) == LOW) {
    states[index state] = 0;
    index state++;
    Serial.println("0");
    delay (250);
  if (digitalRead (buttons[1]) == LOW) {
    states[index state] = 1;
    index state+=1;
    Serial.println("1");
    delay (250);
  if (digitalRead(buttons[2]) == LOW) {
    states[index state] = 2;
    index state+=1;
    Serial.println("2");
    delay (250);
```

Passcode Code loop() Part 1

To check if the passcode has been inputted, we first check if the correct number of values have been entered.

```
// if the user gets to the last index state (correct length of password),
//check if the password matches.
if (index state == SIZE ) {
  if (checkpassword()) {
    digitalWrite (green led pin, HIGH);
    delay(1500);
    digitalWrite (green led pin, LOW);
  else{
    digitalWrite (red led pin, HIGH);
    delay (1500);
    digitalWrite (red led pin, LOW);
  // reset the state array
  index state = 0;
  reset arr();
  Serial.println("RESET");
```

Then, we use checkpassword() to see if the user entered the correct password.

If so, then we turn on green led pin for 1.5 seconds.

If not, we turn on **red led pin** for 1.5 seconds.

Passcode Code - resetarr() & checkpassword()

```
//Reset the array and fill it with garbage values
void reset arr() {
  for (int i = 0; i < SIZE; i++) {
    states[i] = 999;
//Check the password. If ANY of the values in the states array
//do not match the ones in the passcode array, return "false".
//Otherwise, return "true".
bool checkpassword() {
  for ( int i = 0; i < SIZE; i++) {
    if (states[i] != passcode arr[i] ) {
      return false;
  return true;
```

Thank you!
